## Abstract

A-type tri-lacunary heteropolyoxotungstate anions (*e.g.*,  $[\text{PW}_9\text{O}_{34}]^{9-}$ ,  $[\text{AsW}_9\text{O}_{34}]^{9-}$ ,  $[\text{SiW}_9\text{O}_{34}]^{10-}$  and  $[\text{GeW}_9\text{O}_{34}]^{10-}$ ) are multi-dentate oxygen donor ligands that readily form sandwich complexes with actinyl cations ( $\{\text{UO}_2\}^{2+}$ ,  $\{\text{NpO}_2\}^+$ ,  $\{\text{NpO}_2\}^{2+}$  &  $\{\text{PuO}_2\}^{2+}$ ) in near neutral/slightly alkaline aqueous solutions. Two or three actinyl cations are sandwiched between two tri-lacunary anions, with additional cations ( $\text{Na}^+$ ,  $\text{K}^+$  or  $\text{NH}_4^+$ ) also often held within the cluster. Studies thus far have indicated that it is these additional +I cations, rather than the specific actinyl cation, that direct the structural variation in the complexes formed. We now report the structural characterization of the neptunyl(VI) cluster complex  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2] \cdot 7\text{H}_2\text{O}$ . The anion in this complex,  $[\text{Na}(\text{NpO}_2)_2(\text{PW}_9\text{O}_{34})_2]^{13-}$ , contains one  $\text{Na}^+$  cation and two  $\{\text{NpO}_2\}^{2+}$  cations held between two  $[\text{PW}_9\text{O}_{34}]^{9-}$  anions – with an additional partial occupancy  $\text{NH}_4^+$  or  $\{\text{NpO}_2\}^{2+}$  cation also present. In the analogous uranium(VI) system, under similar reaction conditions that includes an excess of  $\text{NH}_4\text{Cl}$  in the parent solution, it was

previously shown that  $[(\text{NH}_4)_2(\text{U}^{\text{VI}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$  is the dominant species in both solution and the crystallized salt. Spectroscopic studies provide further proof of differences in the observed chemistry for the  $\{\text{NpO}_2\}^{2+}/[\text{PW}_9\text{O}_{34}]^{9-}$  and  $\{\text{UO}_2\}^{2+}/[\text{PW}_9\text{O}_{34}]^{9-}$  systems, both in solution and in solid state complexes crystallized from comparable salt solutions. This work reveals that varying the actinide element (Np vs. U) can indeed measurably impact structure and complex stability in the cluster chemistry of actinyl(VI) cations with A-type tri-lacunary heteropolyoxotungstate anions.

## Introduction

Basic research into the chemistry of the actinide elements underpins many aspects of the nuclear fuel cycle including: uranium processing, spent nuclear fuel reprocessing, long-term storage of nuclear waste and environmental clean-up of legacy facilities. The chemistry of the +V and +VI oxidation states for U, Np, Pu and Am is dominated by the linear dioxo actinyl moieties,  $\{\text{An}^{\text{VI}}\text{O}_2\}^{2+}$  and  $\{\text{An}^{\text{V}}\text{O}_2\}^+$ , and these species play an important role in many applied/environmental processes.<sup>[1]</sup> Due to the low radiotoxicity of natural and depleted uranium, and relative ease of performing quantum chemical calculations on closed shell  $5f^0$  actinide ions, our understanding of the chemistry of uranyl(VI) has expanded greatly in recent decades.<sup>[2]</sup> In the past few years synthetic advances have also led to a rapid growth in research into uranyl(V),  $\{\text{UO}_2\}^+$ , an unstable species under most common chemical environments.<sup>[3]</sup> Significantly higher radiological hazards are encountered when working with the transuranic elements, resulting in fewer experimental studies and thus a less complete understanding of the chemistry of the Np, Pu and Am (vs. U) actinyl moieties. With this in mind researchers have

looked to probe coordination environments that allow for the direct comparison of uranyl(VI) species with well characterized structural and spectroscopic properties of analogous transuranic actinyl systems.<sup>[4]</sup>

Heteropolyoxotungstate anions are effective complexants for actinide cations, often stabilizing unusual oxidation states and producing a wide range of structural motifs.<sup>[5]</sup> The study of the interaction of actinyl cations with A-type tri-lacunary heteropolyoxotungstate anions is a prominent subset of such research efforts. These anions are formed from the partial base degradation of Keggin anions (*e.g.*  $[\alpha\text{-PW}_{12}\text{O}_{40}]^{3-}$  to  $[\alpha\text{-PW}_9\text{O}_{34}]^{9-}$ ), and possess six formally unsaturated terminal oxygen atoms that can readily coordinate to other metal centers.<sup>[6]</sup> Two such ligands can complex two or three actinyl cations in sandwich structures in which the equatorial plane of the actinyl moiety is coordinated by two terminal oxygen atoms of one tri-lacunary anion and two terminal oxygen atoms and a bridging oxygen atom of a second tri-lacunary anion (see Figure 1). This coordination environment has now been observed for  $\{\text{UO}_2\}^{2+}$ ,  $\{\text{NpO}_2\}^{2+}$ ,  $\{\text{NpO}_2\}^+$  and  $\{\text{PuO}_2\}^{2+}$ .<sup>[7-14]</sup>

In actinyl tri-lacunary heteropolyoxotungstate complexes the type of salt (NaCl, NH<sub>4</sub>Cl, KCl or KNO<sub>3</sub>) used to crystallize the complex has been shown to play a key role in directing structure. If a sufficient excess of Na<sup>+</sup> was present, the hydrated sodium salts that crystallize contain two actinyl cations and two sodium cations encapsulated between two tri-lacunary anions;  $[\text{Na}_2(\text{U}^{\text{VI}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$ ,  $[\text{Na}_2(\text{U}^{\text{VI}}\text{O}_2)_2(\text{A-SiW}_9\text{O}_{34})_2]^{14-}$ ,  $[\text{Na}_2(\text{U}^{\text{VI}}\text{O}_2)_2(\text{A-GeW}_9\text{O}_{34})_2]^{14-}$  ( $\alpha$  and  $\beta$  isomers) and  $[\text{Na}_2(\text{Np}^{\text{V}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{14-}$ .<sup>[7, 9, 11, 13]</sup> Significantly less excess Na<sup>+</sup> was required to crystallize  $[\text{Na}_2(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A-GeW}_9\text{O}_{34})_2]^{14-}$ ,<sup>[14]</sup> but in all these complexes with encapsulated Na<sup>+</sup>

each of the two sandwiched actinyl cations was bonded by a bridging oxygen of a different tri-lacunary anion. If excess  $K^+$  was used, the crystallized products resulted in the formation of complexes containing three actinyl cations coordinated to two tri-lacunary anions; as seen in both  $[(U^{VI}O_2)_3(A-AsW_9O_{34})_2]^{12-}$  and  $[K_3(Pu^{VI}O_2)_3(A-GeW_9O_{34})_2]^{11-}$  (see Figure 1).<sup>[8, 10]</sup> In the latter case there were no  $K^+$  cations actually trapped within the center of the anionic clusters. With excess  $NH_4Cl$ , the hydrated ammonia salt of  $[(NH_4)_2(U^{VI}O_2)_2(A-PW_9O_{34})_2]^{14-}$  crystallized with one ammonium cation trapped in the sandwich complex and one on the surface of the cluster. Two fully coordinated uranyl cations (~100% occupancy) and a 'vacant' site partially occupied (5%) by a third uranyl were encapsulated in the center of the cluster.<sup>[7]</sup> Similarly, for the  $[(NH_4)_2(U^{VI}O_2)_2(A-AsW_9O_{34})_2]^{14-}$  anion, one  $NH_4^+$  is believed to be coordinated inside the sandwich complex, but evidence for a third partial occupancy  $\{U^{VI}O_2\}^{2+}$  cation was not discussed.<sup>[12]</sup>  $K^+$  analogs of these  $\{UO_2\}^{2+}$  -  $PW_9$  and  $\{UO_2\}^{2+}$  -  $AsW_9$  complexes were also prepared, and partial crystal structures and strong spectroscopic evidence indicated that one  $K^+$  cation is incorporated in the center of the cluster.<sup>[7, 12]</sup> In the complexes with three encapsulated actinyl cations, and those with two encapsulated actinyl cations and one encapsulated mono-positive cation ( $NH_4^+$  or  $K^+$ ), the actinyl moieties bond to the bridging oxygen's of the same tri-lacunary anion. Table 1 lists all the structurally characterized actinyl complexes with A-type tri-lacunary anions.

The present work explores whether the dominant role that cations ( $Na^+$ ,  $K^+$  &  $NH_4^+$ ) play in directing structure in actinyl trilacunary heteropolyoxotungstate complexes extend beyond known  $U^{VI}$ ,  $Np^V$ ,  $Np^{VI}$  and  $Pu^{VI}$  chemistry; with a focus on previously unreported  $Np^{VI}$  chemistry. Due to the stability of  $\{Np^VO_2\}^+$  under most aqueous environments, solution chemistry studies

have tended to focus on this species. However, the chemistry of  $\text{Np}^{\text{IV}}$  and  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  can also be of significance in a range of environmental, waste treatment and spent nuclear fuel processing scenarios.<sup>[1b,15]</sup> Previously it has been shown that complexation of both  $[\text{A-PW}_9\text{O}_{34}]^{9-}$  ('PW<sub>9</sub>') and  $[\text{A-GeW}_9\text{O}_{34}]^{10-}$  ('GeW<sub>9</sub>') to  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  results in a dramatic change in the vis/nIR absorption spectrum of this actinide cation (*c.f.* hydrated  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$ ) and sensitization of  $\text{Np}^{\text{VI}}$  luminescence.<sup>[14]</sup> We now report further investigations<sup>[14]</sup> into the complexation of  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  by A-type tri-lacunary anions; focusing in more detail on the reaction between  $[\text{PW}_9\text{O}_{34}]^{9-}$  and  $\{\text{NpO}_2\}^{2+}$ , and contrasting the chemistry of  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  with previously reported  $\{\text{U}^{\text{VI}}\text{O}_2\}^{2+}$  structural chemistry. This work will reveal that  $\text{Np}^{\text{VI}}$  chemistry does not always mimic  $\text{U}^{\text{VI}}$  chemistry, even with a heteropolyoxometalate ligand system which provides such a well-defined coordination environment.

## Experimental

**Caution!** <sup>237</sup>Np (and daughter isotopes) are radioactive and any chemical manipulations with this isotope should only be conducted in an appropriate radiological laboratory while following all necessary controls and regulations.

**General.**  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  stocks in dilute HCl were generated from an initial sample of  $\text{NpO}_2$ . Dissolution of  $\text{NpO}_2$  in 8 M  $\text{HNO}_3$  with gentle heat and a few drops of 5 % HF led to the formation of  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$ , with partial reduction to  $\{\text{Np}^{\text{V}}\text{O}_2\}^+$  and  $\text{Np}^{\text{IV}}$  over time. Pure  $\{\text{NpO}_2\}^{2+}$  could be generated by ozonolysis followed by addition of base ( $\text{NH}_4\text{OH}$ ) to precipitate solid neptunyl(VI) hydroxide species. These  $\text{Np}^{\text{VI}}$  solids could in turn be washed with  $\text{H}_2\text{O}$  prior to dissolution in HCl. Oxidation state purity, and neptunium concentration were confirmed by

vis/nIR spectroscopy, with assays in 2 M HClO<sub>4</sub> yielding the characteristic [NpO<sub>2</sub>(OH<sub>2</sub>)<sub>5</sub>]<sup>2+</sup> bands, including the 1223 nm transition, with < 1% Np<sup>V</sup> oxidation state impurity.<sup>[16]</sup> Na<sub>8</sub>H[A-β-PW<sub>9</sub>O<sub>34</sub>]-20H<sub>2</sub>O ([PW<sub>9</sub>O<sub>34</sub>]<sup>9-</sup>, PW<sub>9</sub>) was prepared in accordance with the literature method.<sup>[17]</sup> Solution state vis/nIR spectra were recorded on a Cary 6000i spectrometer using both 1 cm and 2 mm path length cells specially adapted for work with high specific activity radionuclides. Solid state vis/nIR spectra were recorded on either a Cary 6000i or a Cary 5 spectrometer with diffuse reflectance attachment in specially adapted glass sample holders, sealed with Teflon plugs. The IR spectrum was recorded as a nujol mull between KBr plates on a Nicolet 6700 FT-IR. The Raman spectrum was recorded on a DXR Smart Raman, Thermo Scientific, with a 780 nm HP laser using a sample previously prepared for diffuse reflectance measurements. The <sup>31</sup>P {<sup>1</sup>H} NMR spectrum was recorded on a Bruker Avance 300 MHz spectrometer at 121.5 MHz, relative to external H<sub>3</sub>PO<sub>4</sub> (85%). The sample was contained in a sealed PTFE NMR tube which was itself contained in a standard 5 mm quartz NMR tube filled with a few drops of D<sub>2</sub>O.

Synthesis. Detailed synthetic methodology for the synthesis of {NpO<sub>2</sub>}<sup>2+</sup> tri-lacunary complexes has been described elsewhere.<sup>[14]</sup> In general excess 'PW<sub>9</sub>' was added to {NpO<sub>2</sub>}<sup>2+</sup> in dilute HCl and the pH raised above pH 7 using dilute NaOH (aq) to ensure complete complexation (defined as complex **1**). Addition of excess KCl led to precipitation of an apple green complex, defined as 'NpO<sub>2</sub><sup>2+</sup> - PW<sub>9</sub> - KCl' (**2**), which could be dissolved in H<sub>2</sub>O and recrystallized by vapour diffusion with MeCN. While crystalline products could readily be obtained using this procedure none proved suitable for X-ray diffraction. Reactions were initially undertaken with 3-4 mg of Np<sup>VI</sup> but the reaction was also scaled up to 15-20 mg {NpO<sub>2</sub>}<sup>2+</sup>. In this reaction a portion of the solution prior to KCl addition was used for <sup>31</sup>P NMR and quantitative UV/vis/nIR analysis (i.e. a

bulk solution of complex **1**). Addition of excess KCl to the remaining solution led to the formation of 'NpO<sub>2</sub><sup>2+</sup> - PW<sub>9</sub>- KCl,' (**2**) with the reaction work-up as described previously.

In contrast, addition of excess NH<sub>4</sub>Cl to the {NpO<sub>2</sub>}<sup>2+</sup>-PW<sub>9</sub> complex in solution (**1**) led to the formation of a salt that was still soluble in the reaction solution. Vapour diffusion of the clear green solution with MeCN produced crystals suitable for single crystal X-ray diffraction, and (NH<sub>4</sub>)<sub>13</sub>[Na(NpO<sub>2</sub>)<sub>2</sub>(A-α-PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>].7H<sub>2</sub>O (**3**) was subsequently structurally characterized.

Single Crystal X-Ray Diffraction. Crystal data for (NH<sub>4</sub>)<sub>13</sub>[Na(NpO<sub>2</sub>)<sub>2</sub>(A-α- PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>].7H<sub>2</sub>O (**3**) were collected on a Bruker D8 with APEX II CCD detector. Chemical formula = H<sub>66</sub> N<sub>13</sub> Na Np<sub>2</sub> O<sub>84</sub> P<sub>2</sub> W<sub>18</sub>, Mw = 5460.89, triclinic space group,  $P\bar{1}$ ,  $a = 12.8871(11)$  Å,  $b = 16.0745(14)$  Å,  $c = 21.5515(19)$  Å,  $\alpha = 99.1340(10)$  °,  $\beta = 95.0050(10)$  °,  $\gamma = 105.8640(10)$  °,  $V = 4199.7(6)$  Å<sup>3</sup>,  $T = 141(2)$  K,  $Z = 2$ , Mo-K $\alpha$  radiation ( $\lambda = 0.71073$  Å),  $\mu = 27.153$  mm<sup>-1</sup>, green-yellow needle with crystal dimensions = 0.22 × 0.10 × 0.08 mm,  $\rho_{\text{calcd}} = 4.318$  g cm<sup>-3</sup>. Intensity data of 42194 reflections were collected in the range  $-15 \leq h \leq 15$ ,  $-19 \leq k \leq 19$ ,  $-26 \leq l \leq 26$ ,  $R_1 = 0.0886$  (for 11406 reflections with  $I \geq 2\sigma$ ),  $wR_2 = 0.1194$  (all data), GOF = 1.210.

## Results and Discussion

Na<sub>8</sub>H[A-β-PW<sub>9</sub>O<sub>34</sub>].20H<sub>2</sub>O ([PW<sub>9</sub>O<sub>34</sub>]<sup>9-</sup>, PW<sub>9</sub>) was added to {NpO<sub>2</sub>}<sup>2+</sup> in a dilute HCl aqueous solution, followed by a pH adjustment to >7. A deep green solution was obtained with vis/NIR solution spectra characteristic of complex formation between A-type tri-lacunary anions and {NpO<sub>2</sub>}<sup>2+</sup> (**1**).<sup>[14]</sup> Addition of excess KCl led to precipitation of a complex containing almost all the Np<sup>VI</sup> present in solution which could be then be dissolved in distilled H<sub>2</sub>O and recrystallized *via* MeCN vapor diffusion. Throughout the rest of this paper we will refer to the products from this

reaction between  $\text{Np}^{\text{VI}}$  and  $\text{PW}_9$  in KCl as  $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$ , complex **2** (as previously described in the experimental section). In contrast, addition of an excess of  $\text{NH}_4\text{Cl}$  to the  $\{\text{NpO}_2\}^{2+} - \text{PW}_9$  solution at near neutral pH yielded a more soluble complex. This solution containing  $\{\text{NpO}_2\}^{2+} - \text{PW}_9 - \text{NH}_4\text{Cl}$  yielded deep green crystals of  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2] \cdot 7\text{H}_2\text{O}$  (**3**).

Single crystal X-ray diffraction analysis of (**1**) revealed two  $[\text{A-}\alpha\text{-PW}_9\text{O}_{34}]^{9-}$  ligands sandwiching two  $\{\text{NpO}_2\}^{2+}$  moieties and a sodium cation (*i.e.*  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$ ), as well as a partial occupancy (0.8) ammonium cation. In addition, there is a third partial occupancy (0.2)  $\{\text{NpO}_2\}^{2+}$  moiety trapped within the cluster which takes the place of the trapped ammonium cation (see Fig. 2). In the presence of the third partial occupancy Np the overall charge of the salt can be balanced by substituting two ammonium cations by two lattice waters (*i.e.*  $(\text{NH}_4)_{11}[\text{Na}(\text{NpO}_2)_3(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2] \cdot 7\text{H}_2\text{O}$ ). Such small changes are normally not observable through X-ray diffraction in a disordered structure. This anion represents a further structural variation in the observed complexation of actinyl cations by A-type trilacunary heteropolyoxotungstate anions.

As with previously reported actinyl A-type tri-lacunary heteropolyoxotungstate complexes,<sup>[7-14]</sup> the Np atoms in  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  are seven coordinate, with the linear  $\text{O}=\text{Np}=\text{O}^{2+}$  core coordinated by two terminal oxygens of one  $[\text{A-}\alpha\text{-PW}_9\text{O}_{34}]^{9-}$  ligand and two terminal and one bridging oxygen of a second  $[\text{A-}\alpha\text{-PW}_9\text{O}_{34}]^{9-}$  ligand. In this structure the Np atoms are coordinated to bridging oxygen atoms of the same  $[\text{A-}\alpha\text{-PW}_9\text{O}_{34}]^{9-}$  ligand. Again, as observed previously, the distortion from pentagonal bipyramidal geometry is caused by the geometric constraints imposed by coordination to three oxygen atoms from one ligand and two oxygen

atoms from the other. The longer An-O bond length observed for the oxygen atom that bridges two tungsten atoms vs. the terminal oxygen atoms bound to only one tungsten atom has also been well documented.<sup>[7-14]</sup> Only the Np-O bond lengths and O-Np-O bond angles for the two full occupancy Np atoms will be discussed in detail. These observed structural parameters for  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  are very similar to the Np-O bond lengths and O-Np-O bond angles in  $[\text{Na}_2(\text{NpO}_2)_2(\text{A-}\alpha\text{-GeW}_9\text{O}_{34})_2]^{14-}$ ,<sup>[14]</sup> yielding additional evidence that changes in overall structure have limited impact on the local actinide coordination environment in actinyl – A-type trilacunary heteropolyoxotungstate complexes (see Table 2). Finally, the Np-O bond lengths in  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  are within the range previously observed for 7 coordinate neptunyl(VI) compounds with oxygen donor ligands. The average Np-O<sub>axial</sub> bond length (1.76(3) Å) is comparable to the 1.705(17) - 1.751(5) Å range observed for  $2\text{NpO}_2\text{SO}_4\cdot\text{H}_2\text{SO}_4\cdot 4\text{H}_2\text{O}$ ,  $\text{NpO}_2(\text{IO}_3)_2\cdot 0.5\text{KCl}\cdot 3.25\text{H}_2\text{O}$ ,  $[\text{NpO}_2\{(\text{OOC})_2\text{C}_6\text{H}_4\}\text{H}_2\text{O}] \cdot \frac{1}{3}\text{H}_2\text{O}$ ,  $\text{K}_2[(\text{NpO}_2)_2(\text{CrO}_4)_3(\text{H}_2\text{O})]\cdot 3\text{H}_2\text{O}$  and  $[(\text{NpO}_2)(\text{CrO}_4)(\text{H}_2\text{O})]\cdot 4\text{H}_2\text{O}$ .<sup>[18-22]</sup> In addition, the average Np-O<sub>equatorial</sub> bond lengths in these five compounds are 2.40(3) Å, 2.39(3) Å, 2.41(5), 2.37(6) and 2.38(3) Å respectively. Again, these values are comparable to the 2.37(9) Å average Np-O<sub>equatorial</sub> bond length for  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$ .<sup>[18-22]</sup> Perhaps the most unusual structural feature of  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  is the incorporation of Na<sup>+</sup> into the cluster, despite the addition of excess NH<sub>4</sub><sup>+</sup> prior to crystallization. A previous solution state <sup>31</sup>P NMR competition study has shown that K<sup>+</sup> and NH<sub>4</sub><sup>+</sup> cations can readily displace Na<sup>+</sup> in  $[\text{Na}_2(\text{UO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{14-}$ ,<sup>[7]</sup> and Na<sup>+</sup> cations have not previously been observed encapsulated within actinyl – A-type tri-lacunary heteropolyoxotungstate complexes crystallized in the presence of either excess K<sup>+</sup> or NH<sub>4</sub><sup>+</sup>.<sup>[8,10,</sup>

<sup>13]</sup> We therefore turned to additional spectroscopic characterization as a means to probe any further differences in the chemical interactions between  $PW_9$  and  $\{NpO_2\}^{2+}$  and  $\{UO_2\}^{2+}$ .

The complexation of  $\{NpO_2\}^{2+}$  by A-type tri-lacunary heteropolyoxotungstate anions yields very distinctive electronic absorption spectra, as indicated previously.<sup>[14]</sup> The spectrum of  $[NpO_2(OH)_5]^{2+}$  in perchloric acid and the spectrum of the solution complex formed between  $\{NpO_2\}^{2+}$  and 'PW<sub>9</sub>' (**1**) are compared in Figure 3. It should be noted that  $PW_9$  was present as the sodium salt, introducing  $Na^+$  into the reaction solution, while the presence of some  $NH_4^+$  from the preparation of  $Np^{VI}$  cannot be discounted. Nevertheless, while the exact structure of the  $Np^{VI}$  -  $PW_9$  - mono-positive cation complex (**2**) in solution cannot be determined it is reasonable to assume 2 or 3  $\{NpO_2\}^{2+}$  cations sandwiched by 2  $PW_9$  anions with 7-coordinate Np in distorted  $D_{5h}$  symmetry. The UV/vis/nIR absorption spectrum of  $[NpO_2(OH)_5]^{2+}$  (between 350-1300 nm, 28,600-7700  $cm^{-1}$ ) contains three main spectral features : i) A band at 1223 nm (8177  $cm^{-1}$ ) likely resulting from an intra-5f transition, ii) Two transitions in the visible region at 476 and 555 nm (21,000 and 18,000  $cm^{-1}$ ), and iii) High energy  $O_{equatorial} \rightarrow Np$  charge transfer transitions (< 400 nm, >25000  $cm^{-1}$ ).<sup>[16, 23]</sup> On complexation by tri-lacunary heteropolyoxotungstate anions the 1223 nm (8177  $cm^{-1}$ ) 5f-5f  $Np^{VI}$  transition shifts to higher energy, in this case to 1137 nm (8795  $cm^{-1}$ ), and decreases in intensity. This blue shift is consistent with previous studies, where an even greater increase in energy, to 1120 nm (8929  $cm^{-1}$ ), and concomitant drop in intensity has recently been observed on nitrate complexation to  $\{NpO_2\}^{2+}$  in 14.5 M  $HNO_3$ .<sup>[24]</sup> At the greatest extreme this 5f-5f transition for  $\{NpO_2\}^{2+}$  dramatically decreases in intensity in the presence of both excess acetate and carbonate, although the reason for this decrease was not discussed.<sup>[25-26]</sup>

Turning to the UV/vis region of the absorption spectrum of **(1)**, substitution of H<sub>2</sub>O by 'PW<sub>9</sub>' equatorial ligands shifts the O→Np charge transfer transition to lower energy (*ca.* 550 nm, 18200 cm<sup>-1</sup>). The most notable feature in the spectrum of the complex is the progression of transitions around 600 nm, the most intense peak occurring at 609 nm (16400 cm<sup>-1</sup>). The progression has a splitting energy of *ca.* 700 cm<sup>-1</sup>, comparable to the energy of O=Np=O  $\nu_1$  in the ground state (*vide infra*). Denning reported the assignment of both LMCT and 5f-5f transitions in this region for both Cs<sub>2</sub>NpO<sub>2</sub>Cl<sub>4</sub> and CsNpO<sub>2</sub>(NO<sub>3</sub>)<sub>3</sub>, with the LMCT transitions exhibiting much more prominent progressions in multiple quanta of  $\nu_1$ .<sup>[27]</sup> In analogy with the {UO<sub>2</sub>}<sup>2+</sup> moiety,<sup>[28]</sup> the prominence of such progressions are indicative of changes in the An-O<sub>axial</sub> bond strength and/or length upon excitation from the ground state to a LMCT state. Comparable vibronic bands at similar energies are also observed for [NpO<sub>2</sub>(CO<sub>3</sub>)<sub>3</sub>]<sup>4-</sup>,<sup>[26,29]</sup> {NpO<sub>2</sub>}<sup>2+</sup> in DMSO,<sup>[30]</sup> and NpO<sub>2</sub>Cl<sub>2</sub> in THF.<sup>[4h]</sup> Similar spectral features are also observed in the visible region for the complexation of {NpO<sub>2</sub>}<sup>2+</sup> with [SiW<sub>11</sub>O<sub>39</sub>]<sup>8-</sup>, as previously reported,<sup>[5q]</sup> although this structurally distinct mono-lacunary heteropolyoxotungstate anion must complex the neptunyl moiety differently than the tri-lacunary anions discussed in this work.

Figure 4 compares the diffuse reflectance spectra of crystalline (NH<sub>4</sub>)<sub>13</sub>[Na(NpO<sub>2</sub>)<sub>2</sub>(A- $\alpha$ -PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>] $\cdot$ 7H<sub>2</sub>O (**3**) and Np<sup>VI</sup>-PW<sub>9</sub>-KCl (**2**) with the previously discussed solution spectrum of {NpO<sub>2</sub>}<sup>2+</sup> + PW<sub>9</sub> (**1**). While subtle variations are observed in the relative intensities of the transitions observed in the visible region (550 nm – 700 nm), more significant differences in both relative intensities and peak energies are observed for the main 5f-5f transition in the NIR region of the spectra. The energy of this transition is almost identical for both the solution spectrum of {NpO<sub>2</sub>}<sup>2+</sup> + PW<sub>9</sub> (**1**) and the solid spectrum of Np<sup>VI</sup>-PW<sub>9</sub>-KCl (**2**), observed at 1138

nm ( $8787\text{ cm}^{-1}$ ) and  $1136\text{ nm}$  ( $8803\text{ cm}^{-1}$ ) respectively. This could be indicative of very similar anionic cluster structures for these solution state and solid state species. In contrast, the 5f-5f transition energy is significantly different for  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]\cdot 7\text{H}_2\text{O}$  (**3**) ( $1147\text{ nm}$ ,  $8718\text{ cm}^{-1}$ ) indicating that the structure observed for  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  (with partial occupancy  $\{\text{NpO}_2\}^{2+}/\text{NH}_4^+$ ) is not replicated in either (**1**) or (**2**).

During the course of the vis/nIR studies it should also be noted that a trace  $\{\text{NpO}_2\}^+$  impurity was useful in determining complete complexation of  $\{\text{NpO}_2\}^{2+}$  with tri-lacunary heteropolyoxotungstate anions. The dominant  $\{\text{NpO}_2\}^+$  5f-5f transition comes at  $980\text{ nm}$  ( $10200\text{ cm}^{-1}$ ) for  $[\text{NpO}_2(\text{OH}_2)_5]^+$  and decreases in energy on complexation by 'PW<sub>9</sub>'.<sup>[13]</sup> By following the disappearance of this  $980\text{ nm}$  transition and appearance of a transition around  $1000\text{-}1010\text{ nm}$  ( $10000 - 9900\text{ cm}^{-1}$ ) all the  $\{\text{NpO}_2\}^+$  can be assumed to be complexed by A-type tri-lacunary anions. Typically  $\{\text{NpO}_2\}^{2+}$  forms stronger complexes with equatorial ligands than  $\{\text{NpO}_2\}^+$ ,<sup>[1b,e]</sup> and thus by inference complete complexation of  $\text{Np}^{\text{V}}$  is indicative of complete complexation of  $\text{Np}^{\text{VI}}$ . This is clearly seen in the solid state diffuse reflectance spectrum of  $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$  complex (**2**) (see E.S.I 1). Also, the presence of a lower Np oxidation state,  $\text{Np}^{\text{V}}$ , makes it highly unlikely that the distinctive  $\text{Np}^{\text{VI}}$  spectroscopic features described here are actually due to the presence of  $\text{Np}^{\text{VII}}$ .  $\text{Np}^{\text{VII}}$  is only stabilized in highly oxidizing environments.<sup>[31]</sup>

Using a sample of the same  $\{\text{NpO}_2\}^{2+}$  and  $\text{PW}_9$  solution from which the vis/nIR spectrum shown in Fig. 3 was obtained (**1**) (*i.e.* with  $\text{Na}^+$  the dominant cation in solution), we recorded the  $^{31}\text{P}$  NMR spectrum. Unfortunately, the results were inconclusive (see E.S.I 2). However, the solid state vibrational spectra (IR/Raman) of  $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$  (**2**) crystallized from that same parent

solution (**1**) were more informative and are shown in Figure 5. Focusing firstly on the IR spectrum, complexation could not be probed by monitoring the changes in the  $\{\text{NpO}_2\}^{2+}$  asymmetric stretch (observed previously at 964 and 919  $\text{cm}^{-1}$  for  $[\text{NpO}_2(\text{H}_2\text{O})_5]^{2+}$  and  $\text{Cs}_2\text{Np}^{\text{VI}}\text{O}_2\text{Cl}_4$  respectively).<sup>[32-33]</sup> This region is obscured by the large W-O stretching range (700  $\text{nm}$  – 1010  $\text{nm}$ ) of the ligand.<sup>[34]</sup> The P-O asymmetric stretch is split into two overlapping bands at 1070 and 1051  $\text{cm}^{-1}$ , comparable to the 1063 and 1057  $\text{cm}^{-1}$  bands observed for  $\text{Na}_{14}[\text{Na}_2(\text{Np}^{\text{V}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2] \cdot 15\text{H}_2\text{O}$ .<sup>[35]</sup> Taken as a fingerprint, the IR spectrum of (**2**) between 600-1100  $\text{cm}^{-1}$  is almost identical to that of  $\text{Na}_{12}[\text{Na}_2(\text{UO}_2)_2(\text{A-PW}_9\text{O}_{34})_2] \cdot 42\text{H}_2\text{O}$ , in which two  $\text{Na}^+$  cations and two  $\{\text{UO}_2\}^{2+}$  moieties are encapsulated by two 'PW<sub>9</sub>' ligands (a 2:2:2 complex), and is distinct from the previously reported spectrum of  $\text{K}_{12}[\text{K}_2(\text{UO}_2)_2(\text{A-PW}_9\text{O}_{34})_2] \cdot x\text{H}_2\text{O}$ .<sup>[7]</sup> This indicates that  $[\text{K}_2(\text{NpO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{14-}$  is not crystallized from solution in the presence of  $\text{K}^+$ , and this is therefore not the anion in (**2**). Rather, the solid state product could contain  $[\text{Na}_2(\text{NpO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$ .

The Raman spectrum of  $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$  (**2**) contains transitions at 964 and 953  $\text{cm}^{-1}$  that are assigned to  $\nu_s(\text{W-O}_t)$  and  $\nu_{as}(\text{W-O}_t)$  respectively, and 889 and 850  $\text{cm}^{-1}$  that are assigned to  $\nu_{as}(\text{W-O}_b)$ .<sup>[34]</sup> This leaves a peak at 781  $\text{cm}^{-1}$  which is assigned to the  $\nu_1\{\text{NpO}_2\}^{2+}$  symmetric stretch, and comes at significantly lower energy than previously observed for  $\text{Cs}_2\text{NpO}_2\text{Cl}_4$  (802  $\text{cm}^{-1}$ ),  $\text{Na}_{14}[\text{Na}_2(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{GeW}_9\text{O}_{34})_2] \cdot 36\text{H}_2\text{O}$  (814  $\text{cm}^{-1}$ ),  $[\text{Np}^{\text{VI}}\text{O}_2(\text{H}_2\text{O})_5]^{2+}$  (856  $\text{cm}^{-1}$ ) and  $\text{NpO}_2(\text{IO}_3)(\text{H}_2\text{O})$  (872  $\text{cm}^{-1}$ ).<sup>[14,21,33,36]</sup> This comparatively low energy transition could be indicative of weaker neptunyl(VI) bonds in this complex, with an even lower energy  $\nu_1\{\text{NpO}_2\}^{2+}$  transition also recently reported for  $[\text{Co}(\text{NH}_3)_6]_2[\text{NpO}_2(\text{OH})_4]_3 \cdot \text{H}_2\text{O}$  (741  $\text{cm}^{-1}$ ).<sup>[37]</sup> This  $\nu_1$

$\{\text{NpO}_2\}^{2+}$  symmetric stretch is comparable to the average vibronic splitting of the bands in the visible diffuse reflectance spectrum of (2), *ca.* 700  $\text{cm}^{-1}$  (Figure 4).

## Conclusions

Many studies have indicated the differences in redox and complex stability between actinyl cations of different element (U, Np, Pu and Am) and oxidation state (V, VI). To date, reports into actinyl complexation by A-type tri-lacunary heteropolyoxotungstate anions ( $[\text{PW}_9\text{O}_{34}]^{9-}$ ,  $[\text{AsW}_9\text{O}_{34}]^{9-}$ ,  $[\text{GeW}_9\text{O}_{34}]^{10-}$  and  $[\text{SiW}_9\text{O}_{34}]^{10-}$ ) have shown almost identical coordination environments around the actinide. In fact, the presence of different counter cations ( $\text{Na}^+$ ,  $\text{K}^+$  and  $\text{NH}_4^+$ ) has been the key factor in determining subtle (but significant) structural variation, not the variation in actinyl cation ( $\{\text{UO}_2\}^{2+}$ ,  $\{\text{NpO}_2\}^+$ ,  $\{\text{NpO}_2\}^{2+}$  or  $\{\text{PuO}_2\}^{2+}$ ). Thus previous studies involving  $\{\text{UO}_2\}^{2+}$  lead to the expectation that the reaction between  $\text{Na}_8\text{H}[\text{A-}\beta\text{-PW}_9\text{O}_{34}]\cdot 20\text{H}_2\text{O}$  and  $\{\text{NpO}_2\}^{2+}$  (aq) would produce  $[\text{Na}_2(\text{NpO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$  in aqueous solution, and  $[(\text{X})_2(\text{NpO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$  after addition of  $\text{XCl}$ , where  $\text{X} = \text{K}$  or  $\text{NH}_4$ . However, in this study, after the addition of  $\text{NH}_4\text{Cl}$  a complex still containing trapped  $\text{Na}^+$ ,  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]\cdot 7\text{H}_2\text{O}$  (**3**), was structurally characterized. Clearly  $\{\text{NpO}_2\}^{2+}$  is behaving differently from  $\{\text{UO}_2\}^{2+}$  in this ligand environment, trapping  $\text{Na}^+$  more effectively in the anionic clusters formed. Complimentary spectroscopic studies, notably UV/vis/nIR and IR, provide evidence for other subtle differences in  $\text{PW}_9 - \{\text{NpO}_2\}^{2+}$  vs  $\text{PW}_9 - \{\text{UO}_2\}^{2+}$  anionic cluster structures in the presence of  $\text{PW}_9$  and  $\text{K}^+/\text{NH}_4^+/\text{Na}^+$ . Therefore, even in the presence of coordinating heteropolyoxotungstate anions that trap actinyl cations in near identical 7-coordinate distorted pentagonal bipyramidal geometries, switching from one actinide element to another (U to Np)

can lead to different structures. This work thus provides further evidence that understanding actinyl chemistry requires experimental studies for all the actinyl (VI/V) cations, not just uranyl(VI).

**Table 1.** Actinyl Complexes with A-Type Tri-lacunary Heteropolyoxotungstate Anions.

Actinyl moiety	<b>+I Cations Trapped in the Cluster</b>		
	Two	One <sup>a</sup>	None <sup>b</sup>
Uranyl(VI)	[Na <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-PW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>12-</sup> [Na <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-SiW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup> [Na <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-GeW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup>	[(NH <sub>4</sub> ) <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-PW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup> [(NH <sub>4</sub> ) <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-AsW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup> [K <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-PW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup> [K <sub>2</sub> (UO <sub>2</sub> ) <sub>2</sub> (A-AsW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup>	[(UO <sub>2</sub> ) <sub>3</sub> (A-AsW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>12-</sup>
Neptunyl(VI)	[Na <sub>2</sub> (NpO <sub>2</sub> ) <sub>2</sub> (A-GeW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup>		
Neptunyl(V)	[Na <sub>2</sub> (NpO <sub>2</sub> ) <sub>2</sub> (A-PW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>14-</sup>		
Plutonyl(VI)			[K <sub>3</sub> (PuO <sub>2</sub> ) <sub>3</sub> (A-GeW <sub>9</sub> O <sub>34</sub> ) <sub>2</sub> ] <sup>11-</sup>

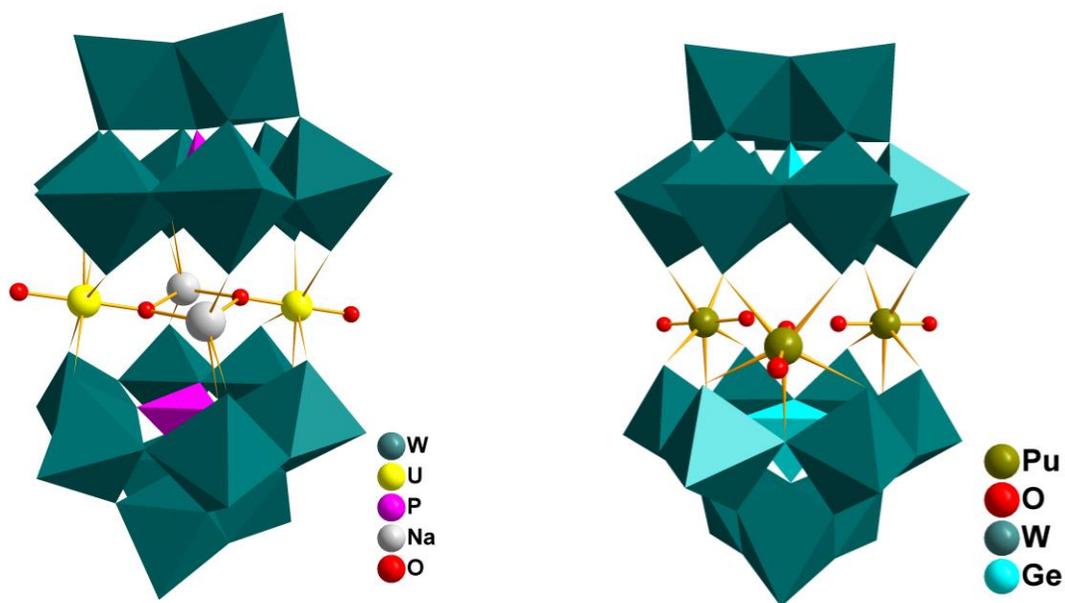

a) Only one of the two +1 cations associated with the formula is actually trapped in the cluster, and the two complexes containing K<sup>+</sup> have not been structurally characterized.

b) None of the K<sup>+</sup> cations associated with the plutonyl(VI) complex are trapped inside the cluster.

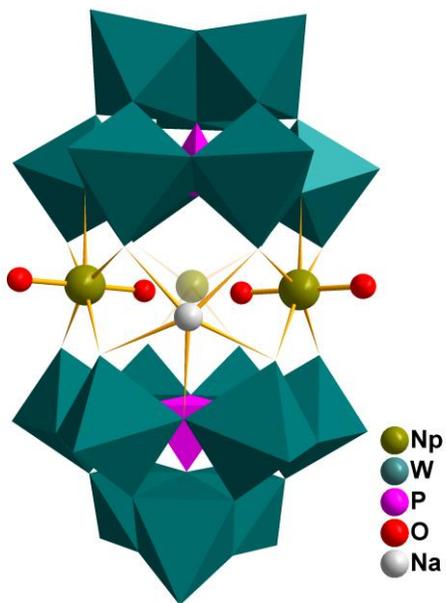

**Table 2.** A comparison of the neptunium coordination environment in  $[\text{Na}(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$  (**3**) (only the full occupancy in inequivalent Np atoms) and  $[\text{Na}_2(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A-}\alpha\text{-GeW}_9\text{O}_{34})_2]^{14-}$ .<sup>[11]</sup>

	$[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$ (Np1 and Np2 data)	$[\text{Na}_2(\text{NpO}_2)_2(\text{A-}\alpha\text{-GeW}_9\text{O}_{34})_2]^{14-}$
<b>Bond lengths (Å)</b>		
Np-O (neptunyl)	1.725(14), 1.758(15), 1.751(14), 1.798(15)	1.77(2), 1.82(3)
Np-O (W-O, terminal)	2.306(13), 2.321(11), 2.335(13), 2.365(14) 2.292(14), 2.297(14), 2.305(14), 2.378(16)	2.25(3), 2.32(3), 2.36(3), 2.39(3)
Np-O (W <sub>2</sub> -O, bridging)	2.552(13), 2.552(14)	2.47(3)
<b>Bond Angles (°)</b>		
O=Np=O (neptunyl)	179.0(7), 177.2(7)	176.3(12)
O-Np-O (equatorial)	62.4(5), 62.1(5), 72.6(5), 79.1(5), 85.0(5) 61.5(4), 63.3(4), 72.9(4), 77.8(4), 85.2(4)	63.7(9), 64.6(10), 74.9(11), 79.6(9), 81.4(10)

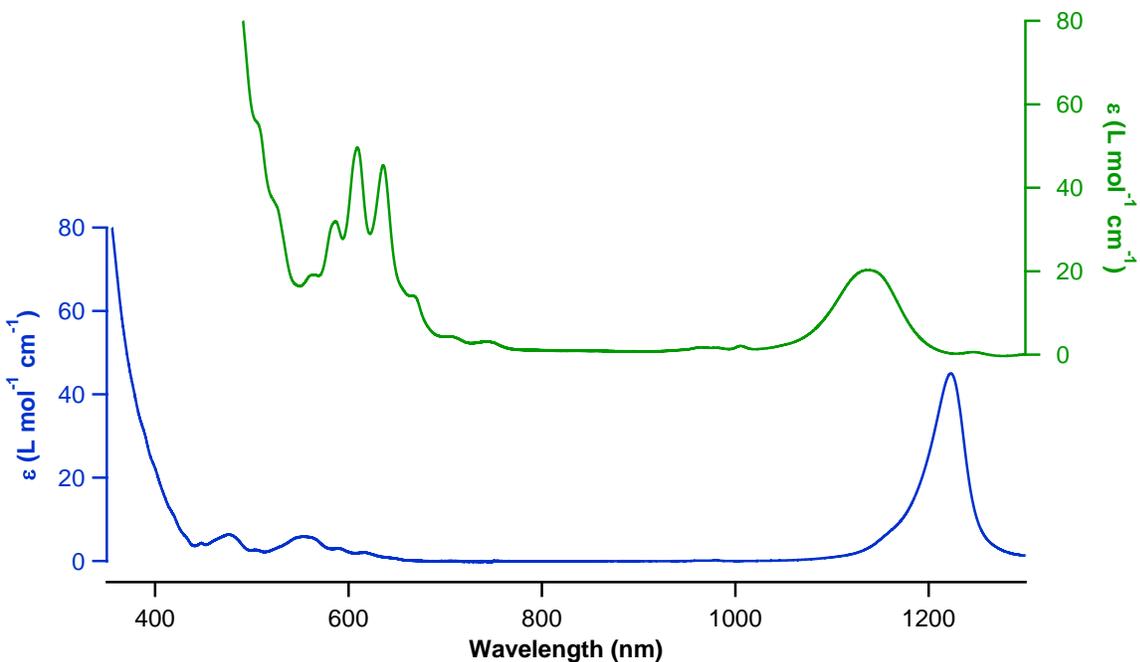

**Figure 1.** Examples of 2:2 and 3:2 actinyl complexes with tri-lacunary heteropolyoxotungstate anions: -  $[\text{Na}_2(\text{UO}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$  and  $[\text{K}_3(\text{PuO}_2)_3(\text{A-GeW}_9\text{O}_{34})_2]^{11-}$  (externally coordinated  $\text{K}^+$  cations removed for clarity).<sup>[7-8]</sup>

**Figure 2.** Combined ball and stick and polyhedral representation of  $[\text{Na}(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{PW}_9\text{O}_{34})_2]^{13-}$ , showing the additional 0.2 occupancy  $\{\text{NpO}_2\}^{2+}$  moiety as partially transparent (rather than the 0.8 occupancy  $\text{NH}_4^+$ ).

**Figure 3.** Vis/nIR Absorption Spectra of (a)  $[\text{NpO}_2(\text{OH}_2)_5]^{2+}$  (5 mmol/L) in 2 M  $\text{HClO}_4$  (left axis) and (b) the reaction between  $\{\text{NpO}_2\}^{2+}$  (11 mmol/L) + A- $[\text{PW}_9\text{O}_{34}]^{9-}$  (1:2 molar ratio) at pH 7.5 (right axis) (**1**). The molar absorptivity values for (**1**) are calculated based on the  $\{\text{NpO}_2\}^{2+}$  concentration and the assumption of complete complexation with formation of a single species in solution.

**Figure 4.** Vis/nIR absorption spectrum of  $\{\text{NpO}_2\}^{2+} + \text{PW}_9$  in pH 7.5 aqueous solution (**1**) (red, left axis) and vis/nIR diffuse reflectance spectra of both the crystalline product prepared from the addition of excess KCl to the complex formed between  $\{\text{NpO}_2\}^{2+}$  and  $\text{A-}[\text{PW}_9\text{O}_{34}]^{9-}$  (**2**) (green trace, right axis) and  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]\cdot 7\text{H}_2\text{O}$  (**3**) (blue trace, right axis). The trace of (**3**) was offset from the trace of (**2**) by  $\times 3.2$  in the y-axis to allow for direct comparison.

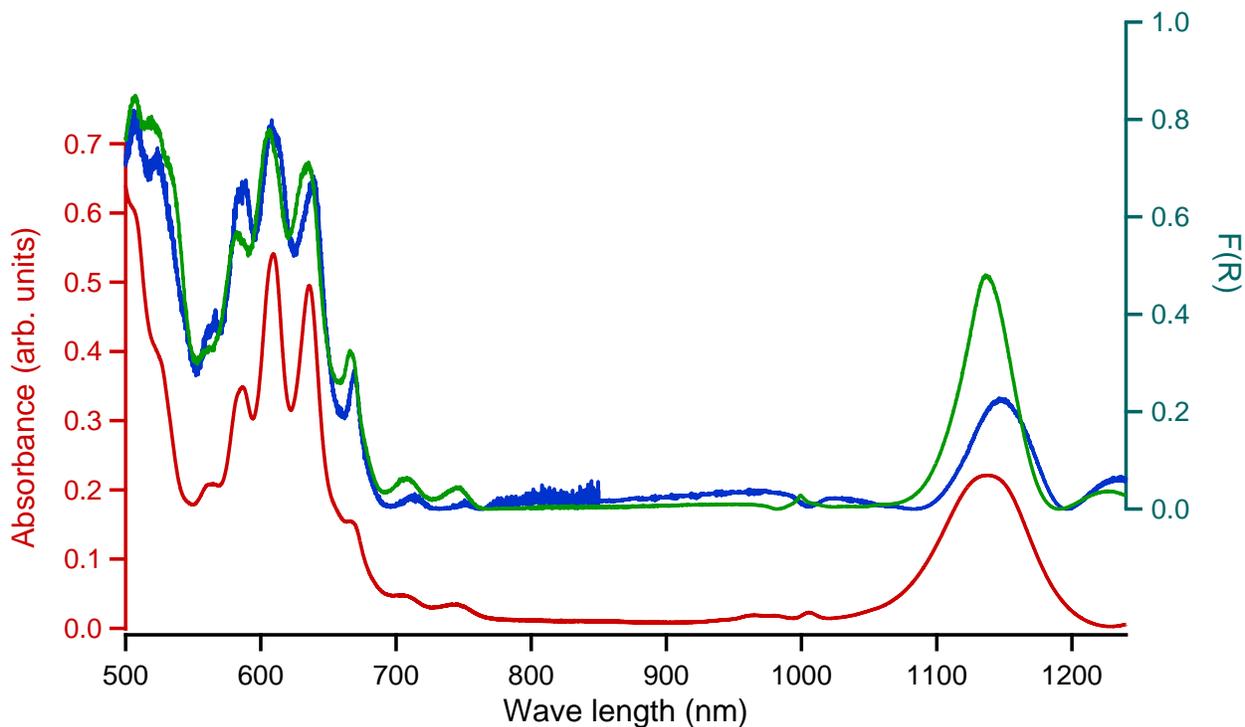

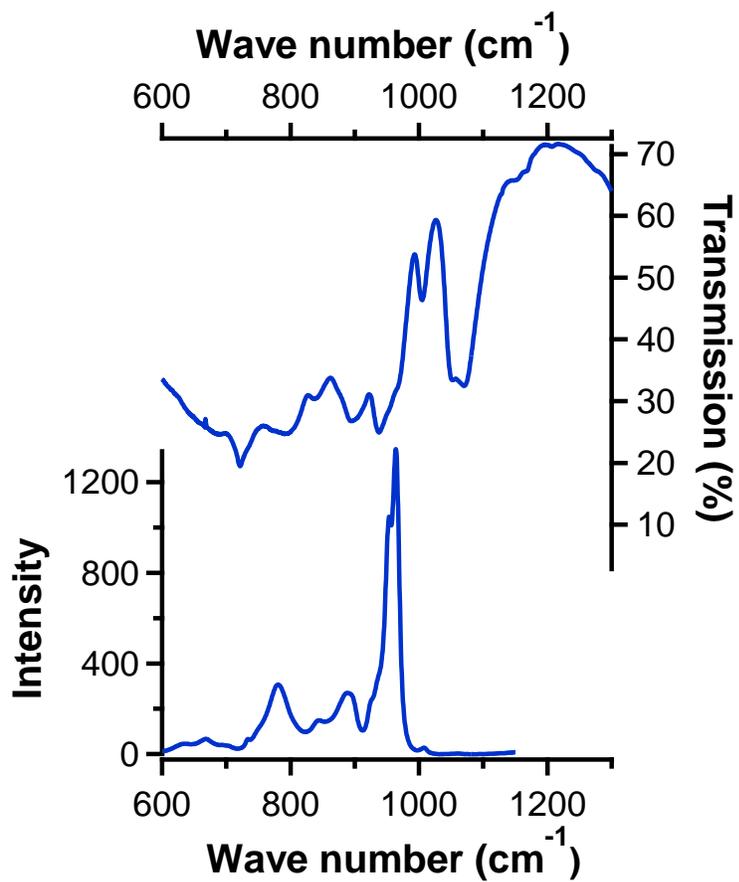

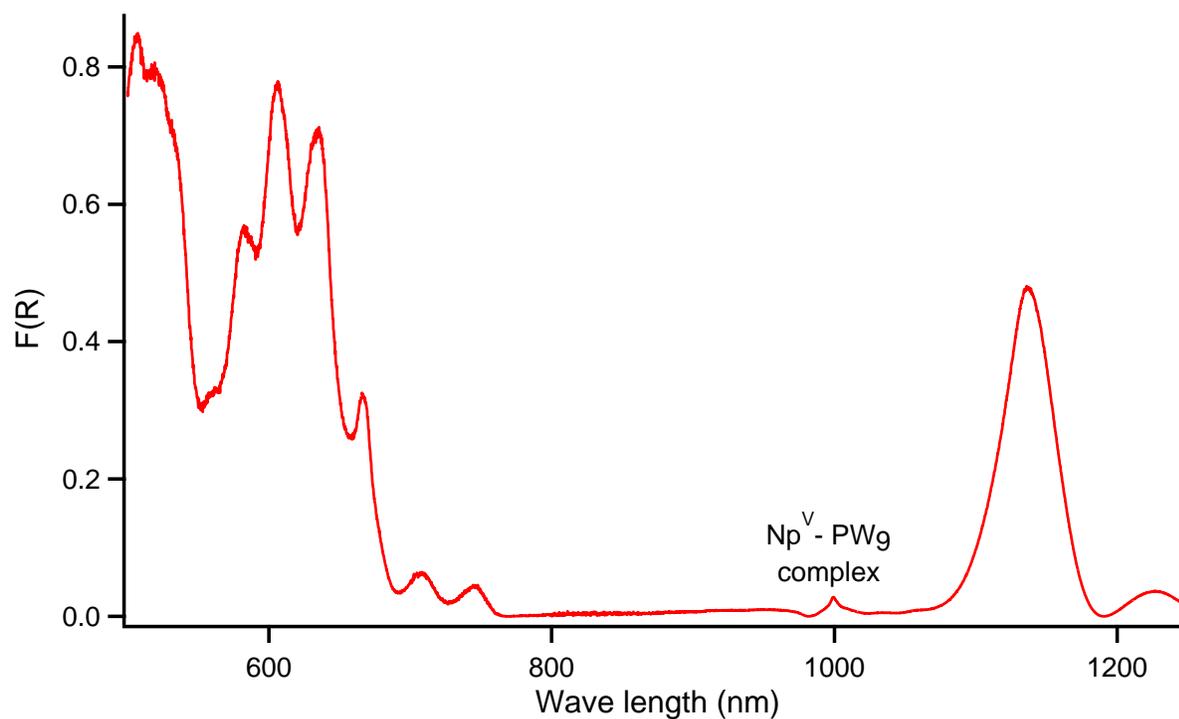

Figure 5. IR (left axis) and Raman (right axis) spectra the crystalline  $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$  (2).

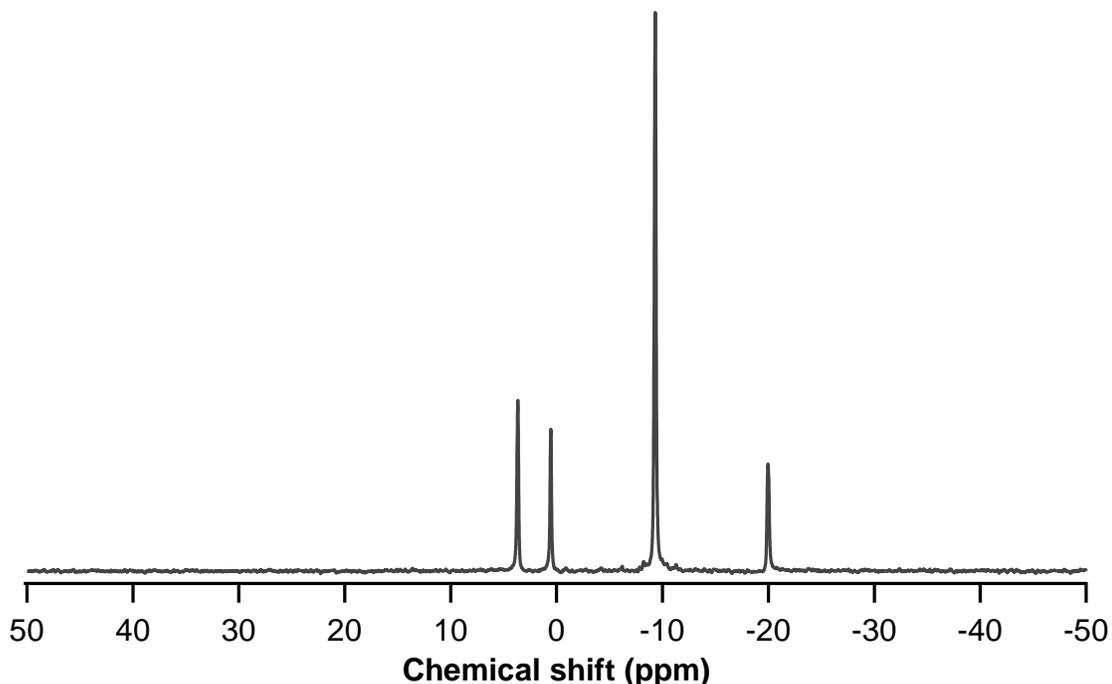

## ELECTRONIC SUPPORTING INFORMATION

E.S.I. 1. The crystalline product prepared from the addition of excess KCl to the complex formed between  $\{\text{Np}^{\text{VI}}\text{O}_2\}^{2+}$  and  $\text{A}[\text{PW}_9\text{O}_{34}]^{9-}$  ( $\text{Np}^{\text{VI}}\text{-PW}_9\text{-KCl}$ ) (**2**), with  $\{\text{Np}^{\text{V}}\text{O}_2\}^+$  impurity observed through the peak at 999 nm assigned to  $[\text{Na}_2(\text{Np}^{\text{V}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{14-}$ .

E.S.I. 2.  $^{31}\text{P}$  NMR of the reaction between 12 mmol  $\{\text{NpO}_2\}^{2+}$  and 24 mmol  $\text{PW}_9$  (**1**) at pH 7.63, sample taken from the same reaction solution used to record the vis/nIR spectrum in Fig 3b.

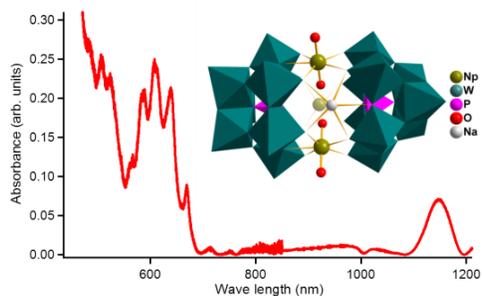

Four main resonances were observed between 10 and -25 ppm, with no additional peaks observed when the scan sweep range was extended to  $\pm 300$  ppm. Assuming 2:2  $[\text{PW}_9\text{O}_{34}]^{9-}:\{\text{NpO}_2\}^{2+}$  complexation, and formation of  $[\text{Na}_2(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{12-}$ , we would expect one  $^{31}\text{P}$  NMR transition attributed to symmetry equivalent 'PW<sub>9</sub>' anions.<sup>[7]</sup> Alternatively, assuming 2:2  $[\text{PW}_9\text{O}_{34}]^{9-}:\{\text{NpO}_2\}^{2+}$  complexation, and formation of  $[\text{Na}(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A-PW}_9\text{O}_{34})_2]^{13-}$ , we would expect two  $^{31}\text{P}$  NMR transition attributed to symmetry inequivalent PW<sub>9</sub> anions. Two  $^{31}\text{P}$  NMR resonances would also be expected for a 3:2 complex,  $[(\text{Np}^{\text{VI}}\text{O}_2)_3(\text{A-PW}_9\text{O}_{34})_2]^{12-}$ . The spectrum was complicated due to the presence of an extra molar equivalent of ligand (2:1  $\text{PW}_9:\{\text{NpO}_2\}^{2+}$

ratio) to ensure complete complexation. At this pH range  $[\text{PW}_{11}\text{O}_{39}]^{7-}$  is the dominant phosphotungstate species in the absence of additional metal cation to stabilize the excess  $[\text{PW}_9\text{O}_{34}]^{9-}$ , which would also result in the presence of free phosphate (as  $\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$ ).<sup>[1]</sup> We therefore assign the peaks at 3.65 and -9.31 ppm to  $\text{H}_2\text{PO}_4^-/\text{HPO}_4^{2-}$  and  $[\text{PW}_{11}\text{O}_{39}]^{7-}$  respectively, the <1ppm deviation from literature values attributed to the presence of  $5f^1$  paramagnetic  $\text{Np}^{\text{VI}}$  in solution. This leaves two resonances at 0.51 & -19.91 ppm which could potentially be assigned to the inequivalent  $\text{PW}_9$  ligands in  $[\text{Na}(\text{Np}^{\text{VI}}\text{O}_2)_2(\text{A}-\text{PW}_9\text{O}_{34})_2]^{13}$  or  $[(\text{Np}^{\text{VI}}\text{O}_2)_3(\text{A}-\text{PW}_9\text{O}_{34})_2]^{12-}$ . In contrast, for the  $\text{UO}_2^+-\text{PW}_9^-\text{K}^+/\text{Na}^+/\text{NH}_4^+$  systems the  $^{31}\text{P}$  NMR peaks all fell within the range -9.5 to -11 ppm. The significant shift in resonances vs. the uranyl analog could be attributed to the presence of an unpaired electron in  $\text{Np}^{\text{VI}}$ , although there is no paramagnetic broadening of either peak which would perhaps be expected for a  $\text{Np}^{\text{VI}}$  complex.<sup>[1]</sup>

## Table of Contents Graphic and Synopsis

The reaction between  $\{\text{NpO}_2\}^{2+}$  and the A-type tri-lacunary heteropolyoxotungstate anion  $[\alpha\text{-PW}_9\text{O}_{34}]^{9-}$  in the presence of  $\text{NH}_4\text{Cl}$  led to the crystallization and structural characterization of  $(\text{NH}_4)_{13}[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]\cdot 7\text{H}_2\text{O}$ . The anion in this compound,  $[\text{Na}(\text{NpO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{13-}$ , is distinct from the anion characterized in the analogous  $\{\text{UO}_2\}^{2+}$  system,  $[(\text{NH}_4)_2(\text{UO}_2)_2(\text{A-}\alpha\text{-PW}_9\text{O}_{34})_2]^{12-}$ . Additional measurements point to distinctive spectroscopic signatures for  $\{\text{NpO}_2\}^{2+}$  complexation with A-type tri-lacunary anions, and to the challenges associated with probing subtle structural variation.
